

# Digital Design & Computer Arch.

## Lecture 3a: Mysteries in Comp. Arch.

Prof. Onur Mutlu

ETH Zürich

Spring 2020

27 February 2020

# Four Mysteries, Continued

---

- Meltdown & Spectre (2017-2018)
- Rowhammer (2012-2014)
- Memories Forget: Refresh (2011-2012)
- Memory Performance Attacks (2006-2007)

# Mystery #3: DRAM Refresh

# Recall: DRAM Refresh

---

- DRAM capacitor charge leaks over time
- The memory controller needs to refresh each row periodically to restore charge
  - Activate each row every  $N$  ms
  - Typical  $N = 64$  ms
- Downsides of refresh
  - **Energy consumption**: Each refresh consumes energy
  - **Performance degradation**: DRAM rank/bank unavailable while refreshed
  - **QoS/predictability impact**: (Long) pause times during refresh
  - **Refresh rate limits DRAM capacity scaling**

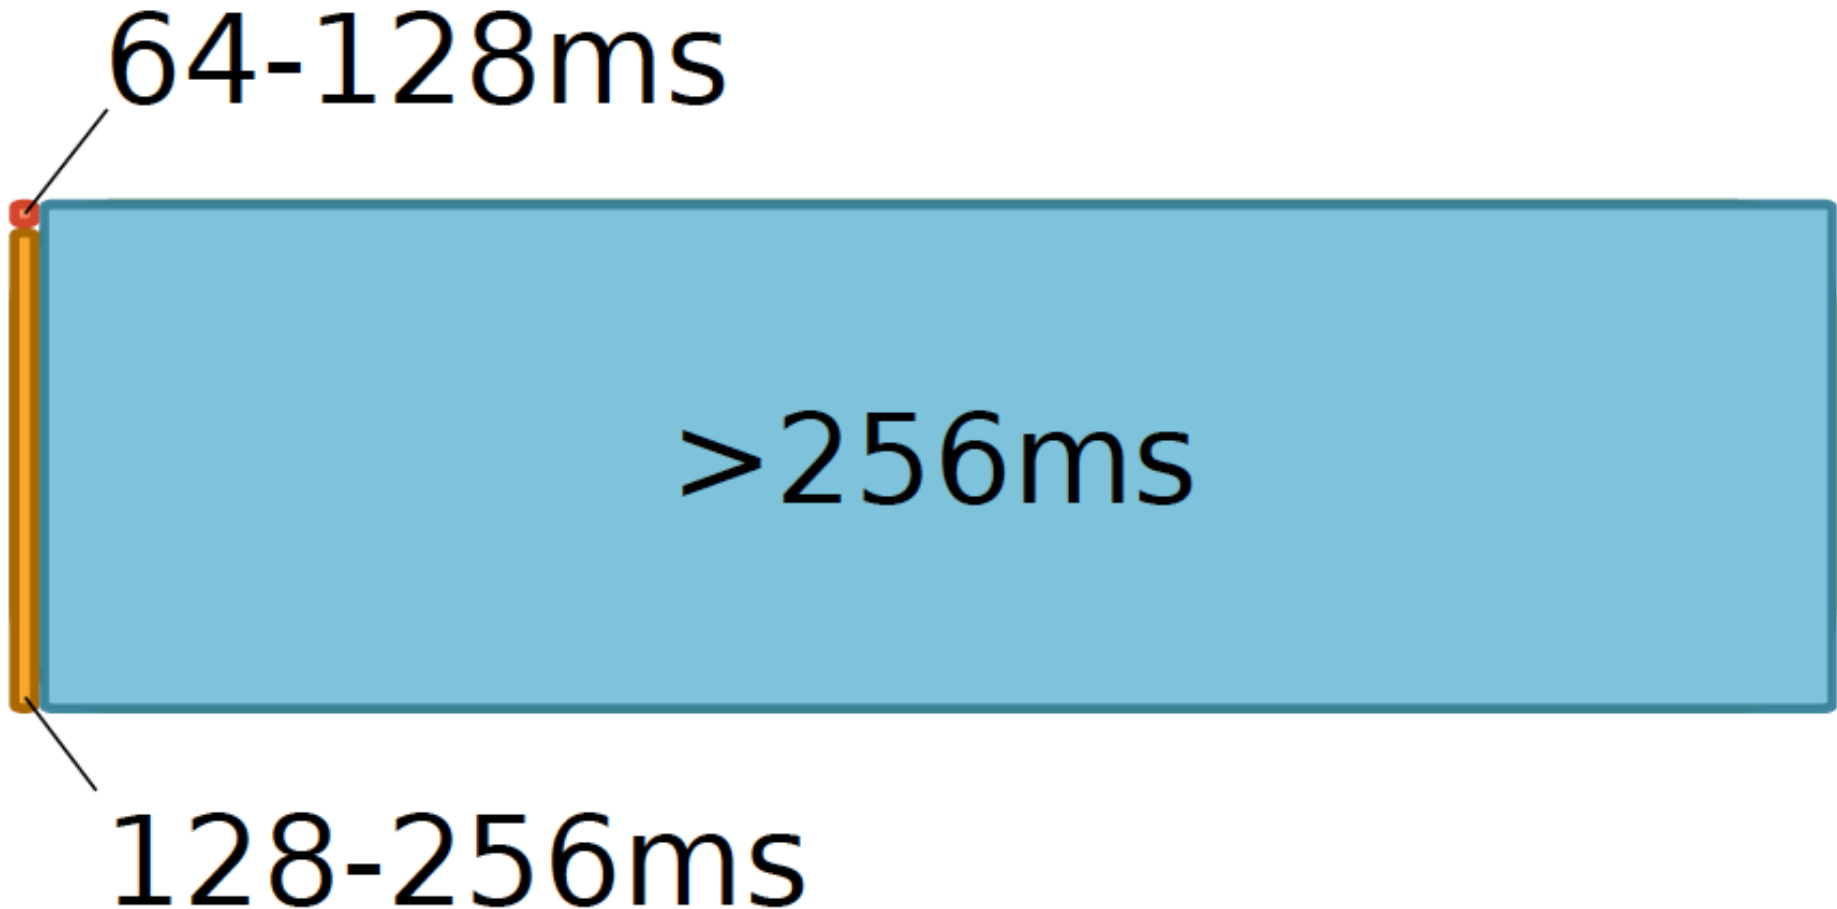

# Recall: How Do We Solve the Problem?

---

- Observation: All DRAM rows are refreshed every 64ms.
- Critical thinking: Do we need to refresh all rows every 64ms?
- What if we knew what happened underneath and exposed that information to upper layers?

# Underneath: Retention Time Profile of DRAM

---

# Aside: Why Do We Have Such a Profile?

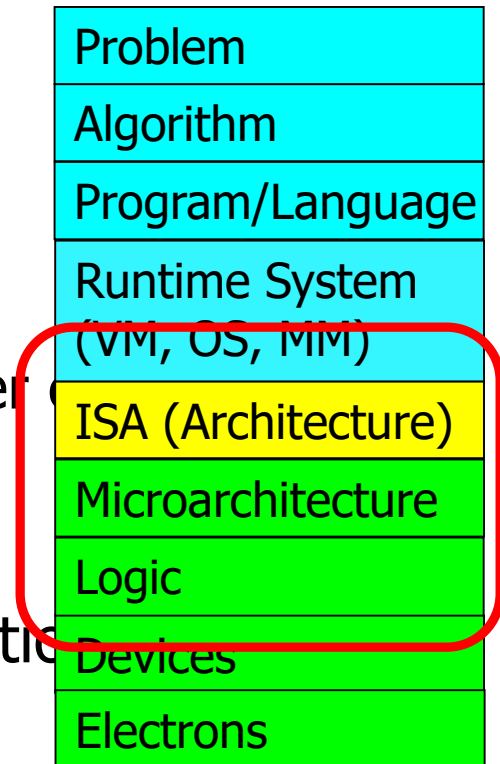

---

- Answer: Manufacturing is not perfect
- Not all DRAM cells are exactly the same
- Some are more leaky than others
- This is called **Manufacturing Process Variation**

# Opportunity: Taking Advantage of This Profile

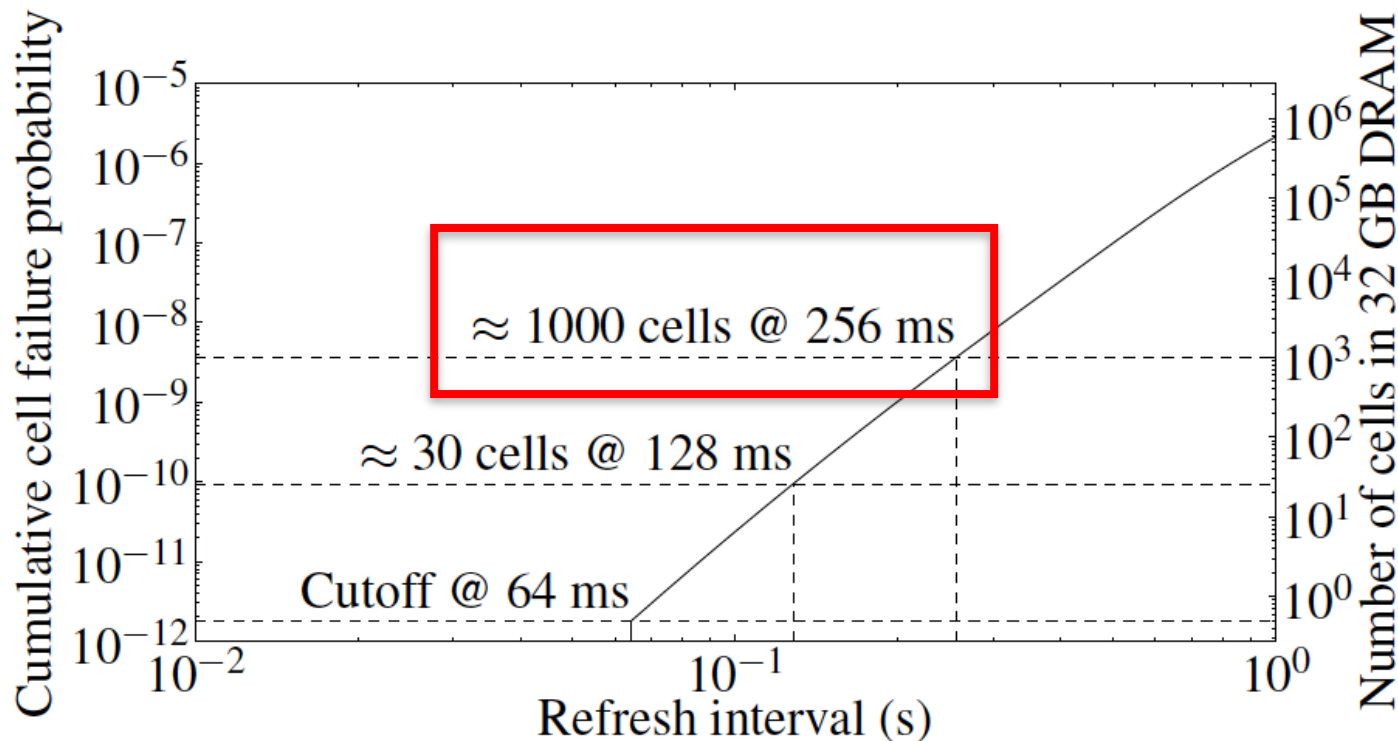

---

- Assume we know the retention time of each row exactly
- What can we do with this information?
- Who do we expose this information to?
- How much information do we expose?
  - Affects hardware/software overhead, power, verification complexity, cost
- How do we determine this profile information?
  - Also, who determines it?

# Retention Time of DRAM Rows

- Observation: Overwhelming majority of DRAM rows can be refreshed much less often without losing data

**Key Idea of RAIDR: Refresh weak rows more frequently,  
all other rows less frequently**

# RAIDR: Eliminating Unnecessary DRAM Refreshes

Liu, Jaiyen, Veras, Mutlu,  
RAIDR: Retention-Aware Intelligent DRAM Refresh  
ISCA 2012.

# RAIDR: Mechanism

---

1. **Profiling:** Identify the retention time of all DRAM rows

64-128ms

> 256ms

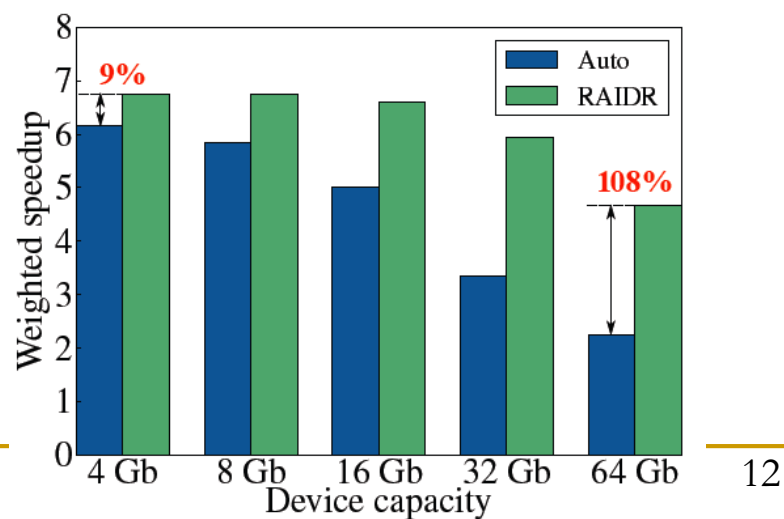

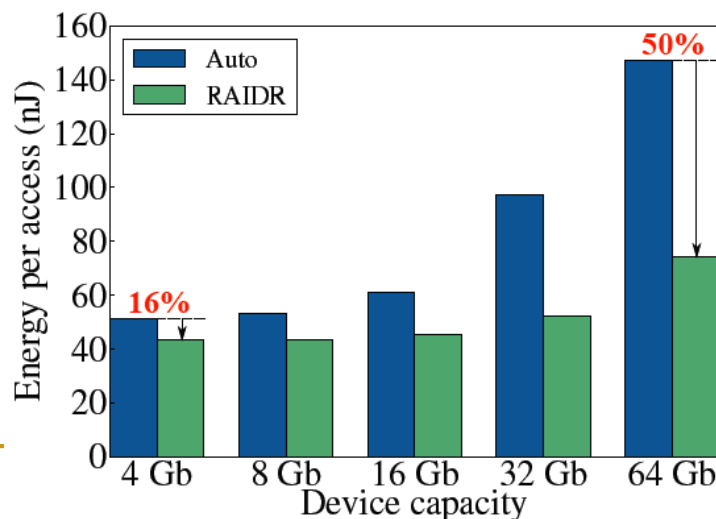

1.25KB storage in controller for 32GB DRAM memory

128-256ms

→ check the bins to determine refresh rate of a row

# RAIDR: Results and Takeaways

- System: 32GB DRAM, 8-core; Various workloads
- RAIDR hardware cost: 1.25 kB (2 Bloom filters)
- Refresh reduction: 74.6%
- Dynamic DRAM energy reduction: 16%
- Idle DRAM power reduction: 20%
- Performance improvement: 9%
- Benefits increase as DRAM scales in density

# Takeaway

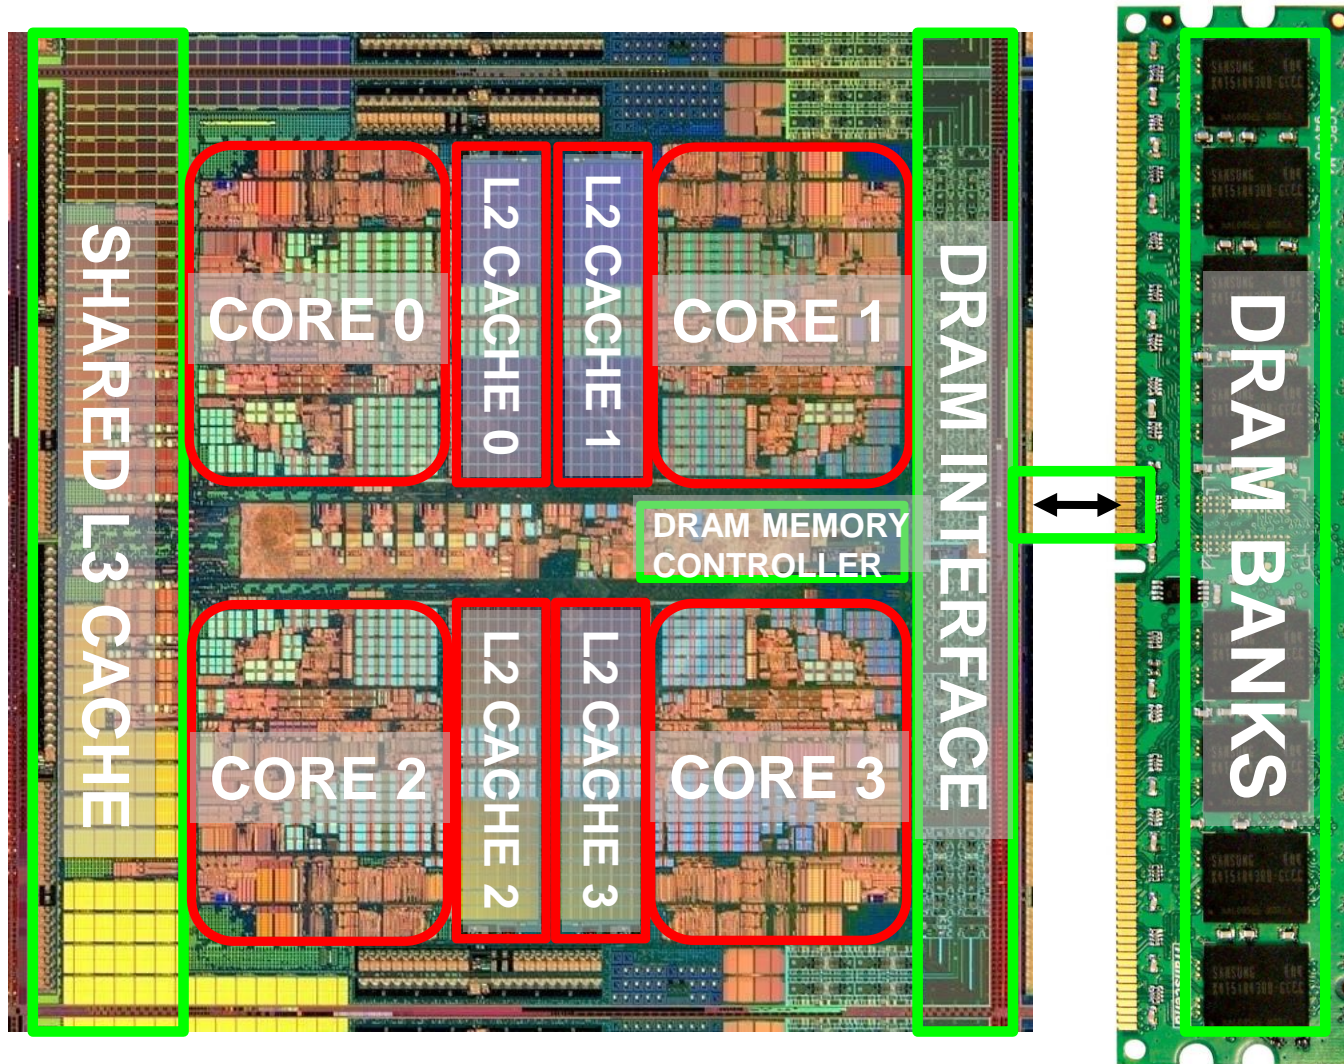

---

Breaking the abstraction layers  
(between components and  
transformation hierarchy levels)  
and knowing what is underneath  
enables you to **understand** and  
**solve** problems

# Mystery #4: Memory Performance Attacks

# Multi-Core Systems

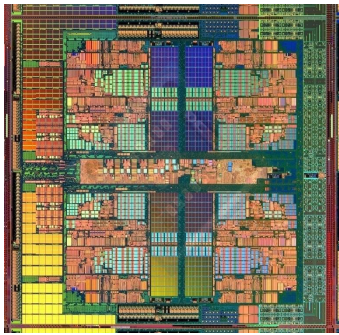

Multi-Core  
Chip

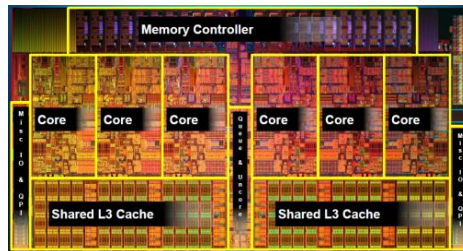

\*Die photo credit: AMD Barcelona

# A Trend: Many Cores on Chip

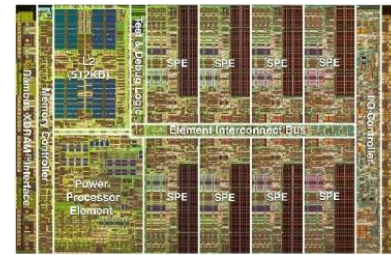

- **Simpler and lower power** than a **single large core**
- Parallel processing on single chip → faster, new applications

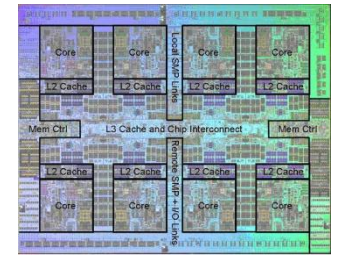

AMD Barcelona  
4 cores

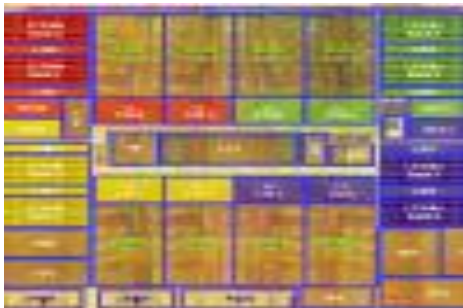

Intel Core i7  
8 cores

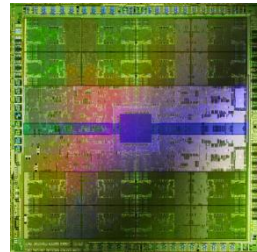

IBM Cell BE  
8+1 cores

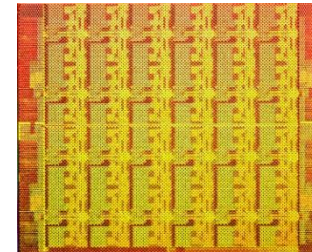

IBM POWER7  
8 cores

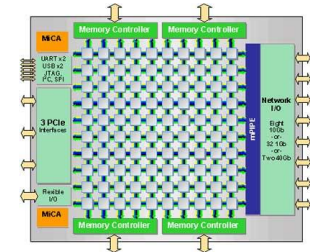

Sun Niagara II  
8 cores

Nvidia Fermi  
448 "cores"

Intel SCC  
48 cores, networked

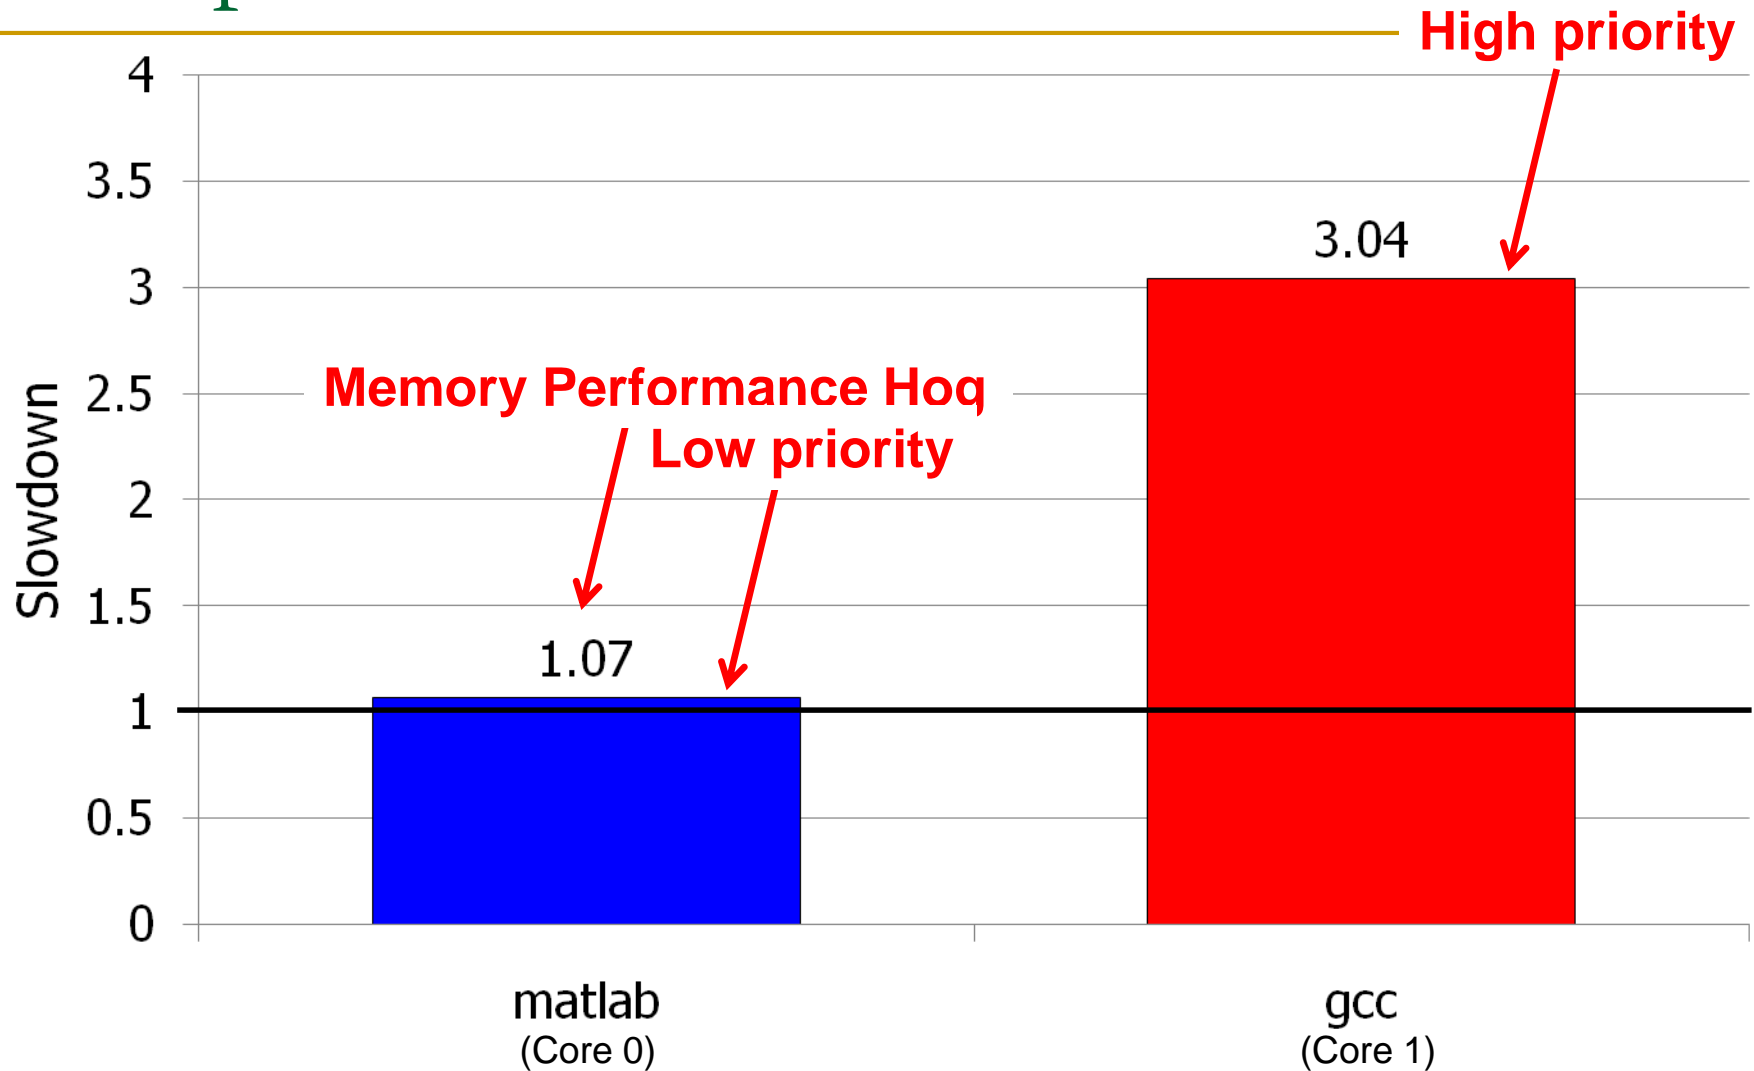

Tiler TILE Gx  
100 cores, networked

# Many Cores on Chip

---

- What we want:
  - N times the system performance with N times the cores
- What do we get today?

# Unexpected Slowdowns in Multi-Core

Moscibroda and Mutlu, “[Memory performance attacks: Denial of memory service in multi-core systems](#),” USENIX Security 2007.

# Three Questions

---

- Can you figure out **why the applications slow down** if you do not know the underlying system and how it works?
- Can you figure out **why there is a disparity in slowdowns** if you do not know how the system executes the programs?
- Can you **fix the problem** without knowing what is happening “underneath”?

# Three Questions

---

- Why is there any slowdown?
- Why is there a disparity in slowdowns?
- How can we solve the problem if we do not want that disparity?
  - What do we want (the system to provide)?

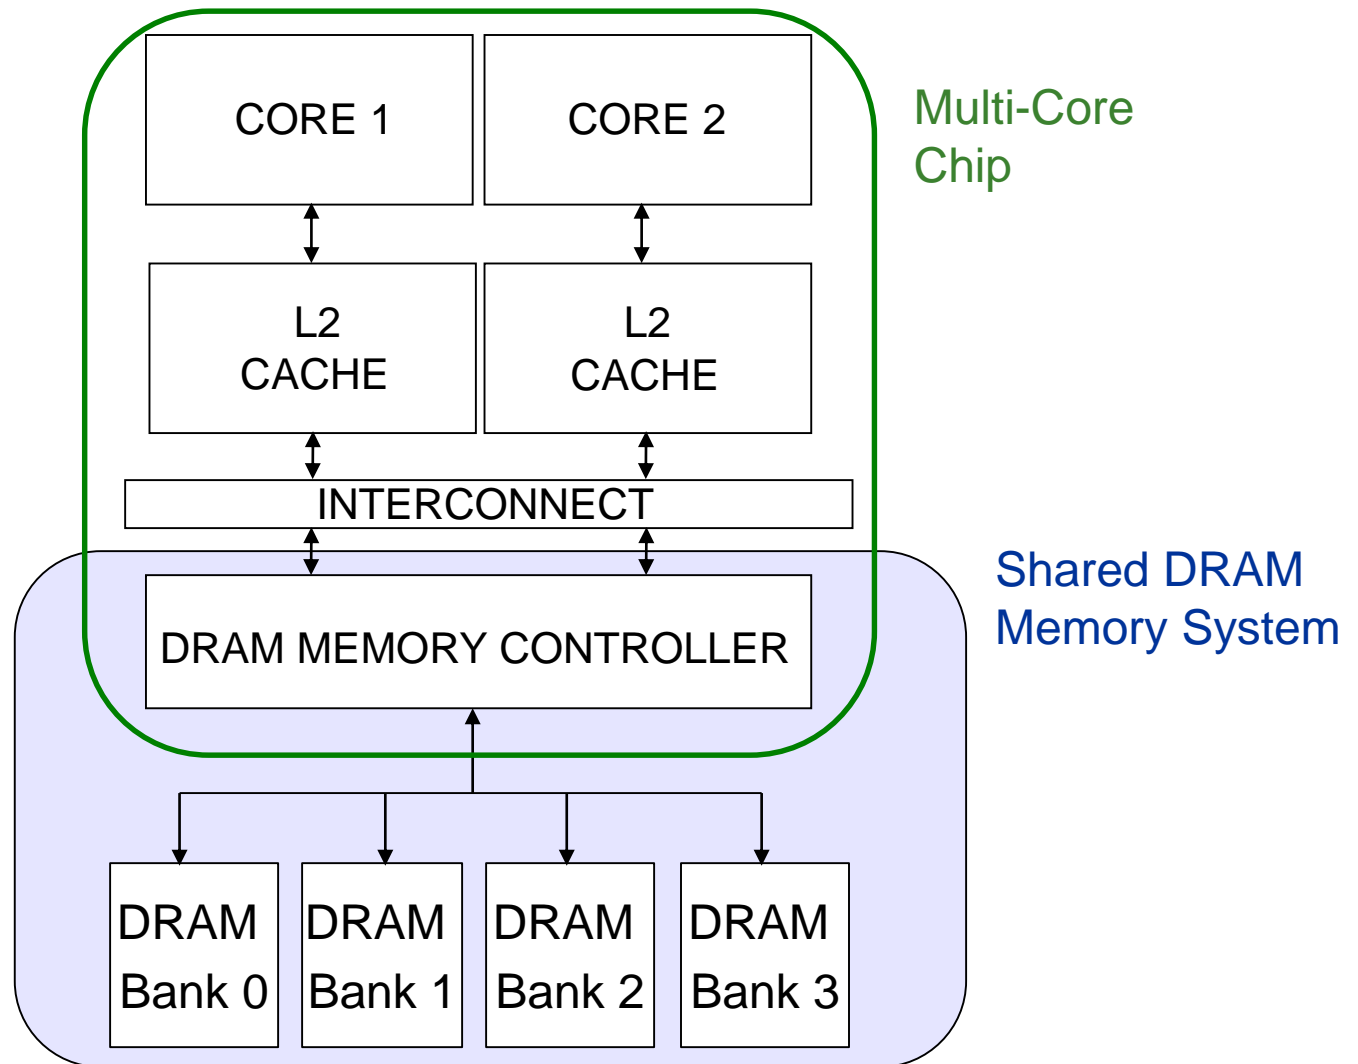

# Why Is This Important?

---

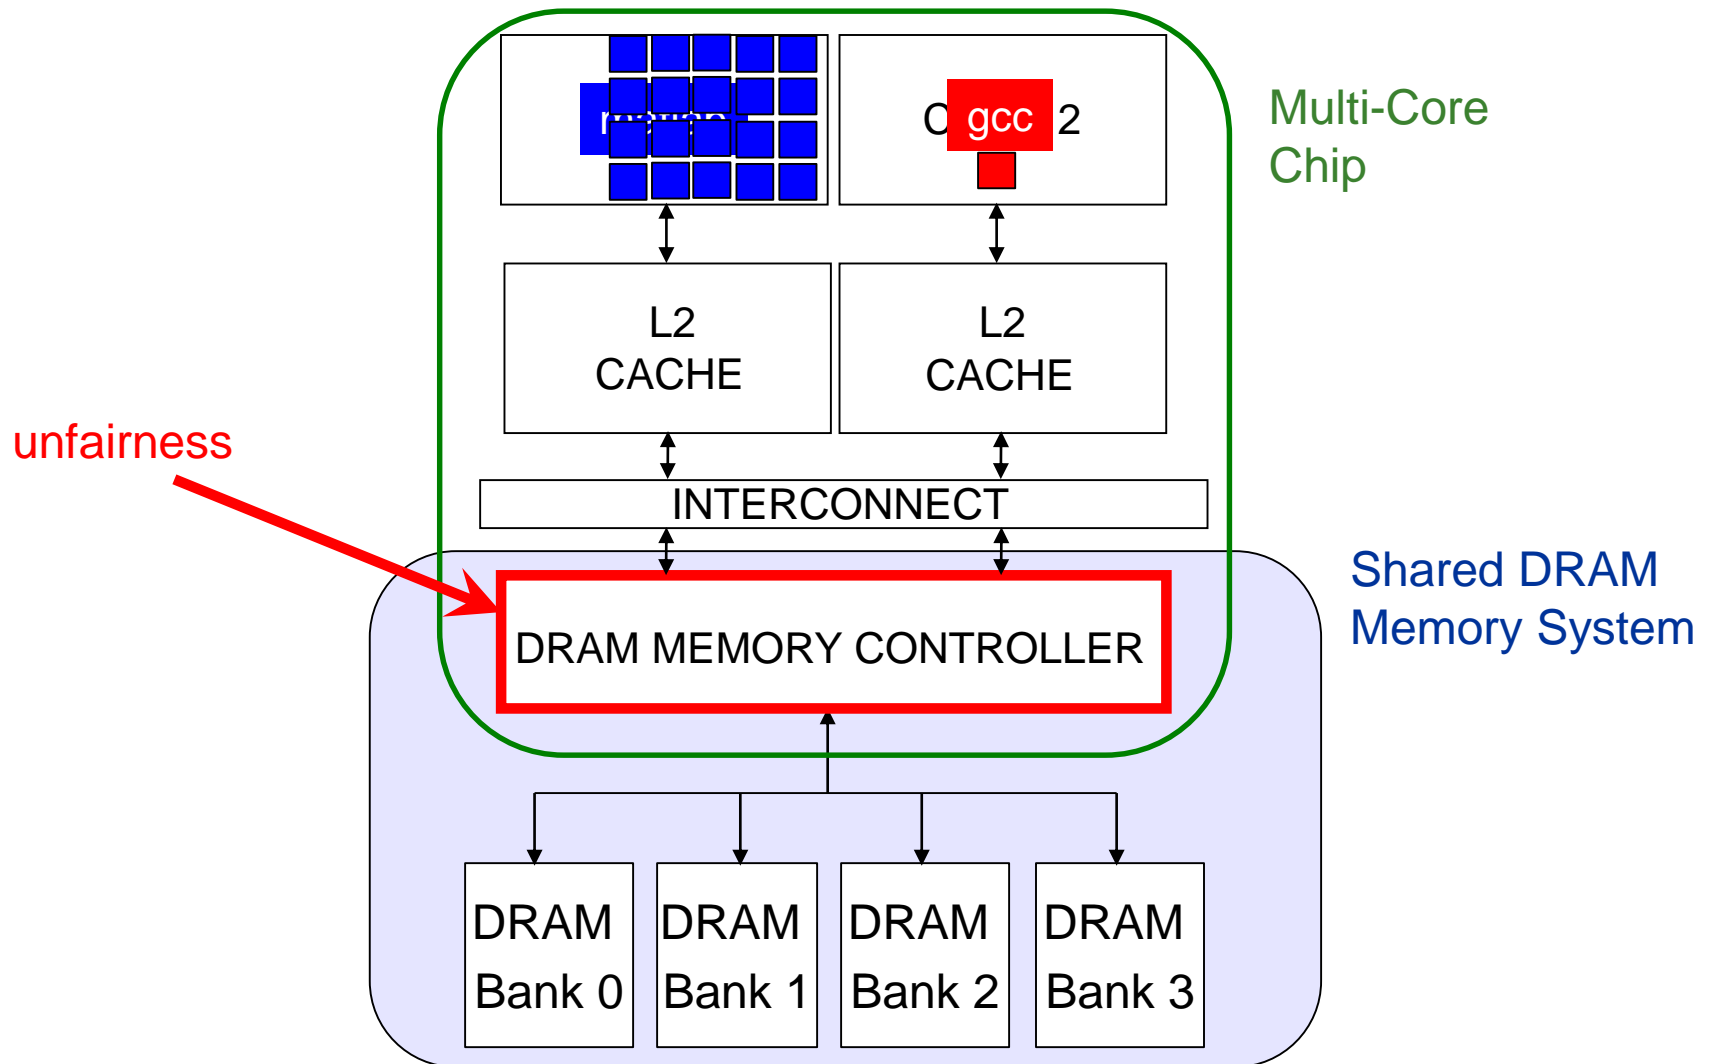

- We want to execute applications in parallel in multi-core systems → consolidate more and more
  - Cloud computing
  - Mobile phones
- We want to mix different types of applications together
  - those requiring QoS guarantees (e.g., video, pedestrian detection)
  - those that are important but less so
  - those that are less important
- We want the system to be **controllable and high performance**

# Why the Disparity in Slowdowns?

---

# Why the Disparity in Slowdowns?

Data

# DRAM Controllers

---

- A row-conflict memory access takes significantly longer than a row-hit access
- Current controllers take advantage of this fact
- Commonly used scheduling policy (FR-FCFS) [Rixner 2000]\*
  - (1) **Row-hit first:** Service row-hit memory accesses first
  - (2) **Oldest-first:** Then service older accesses first
- This scheduling policy aims to maximize DRAM throughput

\*Rixner et al., “Memory Access Scheduling,” ISCA 2000.

\*Zuravleff and Robinson, “Controller for a synchronous DRAM ...,” US Patent 5,630,096, May 1997.

# The Problem

---

- Multiple applications share the DRAM controller
- DRAM controllers designed to maximize DRAM data throughput
- DRAM scheduling policies are unfair to some applications
  - Row-hit first: unfairly prioritizes apps with high row buffer locality
    - Threads that keep on accessing the same row
  - Oldest-first: unfairly prioritizes memory-intensive applications
- DRAM controller vulnerable to denial of service attacks
  - Can write programs to exploit unfairness

# A Memory Performance Hog

---

```
// initialize large arrays A, B

for (j=0; j<N; j++) {
    index = j*linesize; streaming
    A[index] = B[index]; (in sequence)
    ...
}
```

## STREAM

- Sequential memory access
- Very high row buffer locality (96% hit rate)
- Memory intensive

```
// initialize large arrays A, B

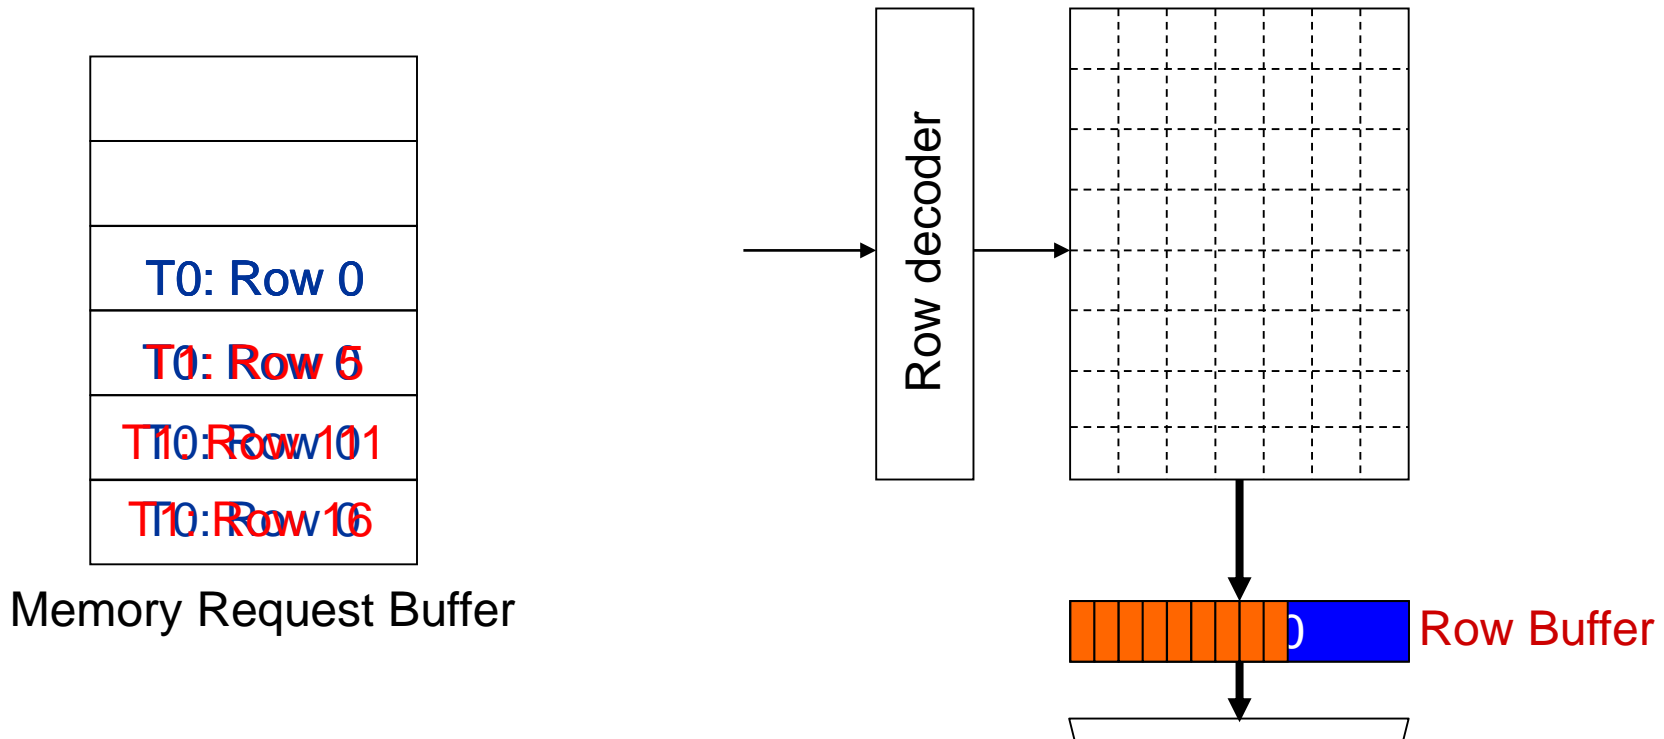

for (j=0; j<N; j++) {
    index = rand(); random
    A[index] = B[index];
    ...
}
```

## RANDOM

- Random memory access
- Very low row buffer locality (3% hit rate)
- Similarly memory intensive

Moscibroda and Mutlu, “[Memory Performance Attacks](#),” USENIX Security 2007.

# What Does the Memory Hog Do?

Row size: 8KB, request size: 64B

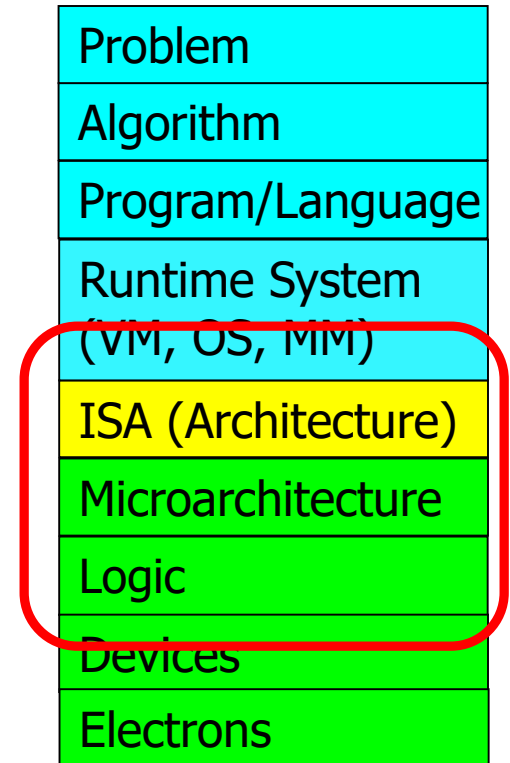

128 (8KB/64B) requests of STREAM serviced  
before a single request of RANDOM

Moscibroda and Mutlu, “Memory Performance Attacks,” USENIX Security 2007.

# Now That We Know What Happens Underneath

---

- How would you solve the problem?
- What is the right place to solve the problem?
  - ❑ Programmer?
  - ❑ System software?
  - ❑ Compiler?
  - ❑ Hardware (Memory controller)?
  - ❑ Hardware (DRAM)?
  - ❑ Circuits?
- Two other goals of this course:
  - ❑ Enable you to **think critically**
  - ❑ Enable you to **think broadly**

# Takeaway I

---

Breaking the abstraction layers  
(between components and  
transformation hierarchy levels)  
and knowing what is underneath  
enables you to **understand** and  
**solve** problems

# Takeaway II

---

Cooperation between  
multiple components and layers  
can enable  
more effective  
solutions and systems

# Recap: Mysteries No Longer!

---

- Meltdown & Spectre (2017-2018)
- Rowhammer (2012-2014)
- Memories Forget: Refresh (2011-2012)
- Memory Performance Attacks (2006-2007)

# Takeaways

# Takeaways

---

- It is an exciting time to be understanding and designing computing architectures
- Many challenging and exciting problems in platform design
  - That no one has tackled (or thought about) before
  - That can have huge impact on the world's future
- Driven by huge hunger for data (Big Data), new applications (ML/AI, graph analytics, genomics), ever-greater realism, ...
  - We can easily collect more data than we can analyze/understand
- Driven by significant difficulties in keeping up with that hunger at the technology layer
  - Five walls: Energy, reliability, complexity, security, scalability

# Computer Architecture as an Enabler of the Future

# Assignment: Required Lecture Video

---

- Why study computer architecture?
- Why is it important?
- **Future Computing Architectures**
- **Required Assignment**
  - **Watch** Prof. Mutlu's inaugural lecture at ETH and understand it
  - <https://www.youtube.com/watch?v=kgiZISOcGFM>
- **Optional Assignment – for 1% extra credit**
  - **Write a 1-page summary** of the lecture and email us
    - What are your key takeaways?
    - What did you learn?
    - What did you like or dislike?
    - Submit your summary to [Moodle](#)

# Bloom Filters

# Approximate Set Membership

---

- Suppose you want to quickly find out:
  - whether an element belongs to a set
- And, you can tolerate mistakes of the sort:
  - The element is actually **not** in the set, but you are incorrectly told that it is → false positive
- But, you cannot tolerate mistakes of the sort:
  - The element is actually in the set, but you are incorrectly told that it is **not** → false negative
- Example task: You want to quickly identify all Mobile Phone Model X owners among all possible people in the world
  - Perhaps you want to give them free replacement phones

# Example Task

---

- World population
  - ~8 billion (and growing)
  - 1 bit per person to indicate Model X owner or not
  - $2^{33}$  bits needed to represent the entire set accurately
    - 8 Gigabits → large storage cost, slow access
- Mobile Phone Model X owner population
  - Say 1 million (and growing)
- Can we represent the Model X owner set approximately, using a much smaller number of bits?
  - Record the ID's of owners in a much smaller Bloom Filter

# Example Task II

---

- DRAM row population
  - ~8 billion (and growing)
  - 1 bit per row to indicate Refresh-often or not
  - $2^{33}$  bits needed to represent the entire set accurately
    - 8 Gigabits → large storage cost, slow access
- Refresh-often population
  - Say 1 million
- Can we represent Refresh-often set approximately, using a much smaller number of bits?
  - Record the ID's of Refresh-Often rows in a much smaller Bloom Filter

# Bloom Filter

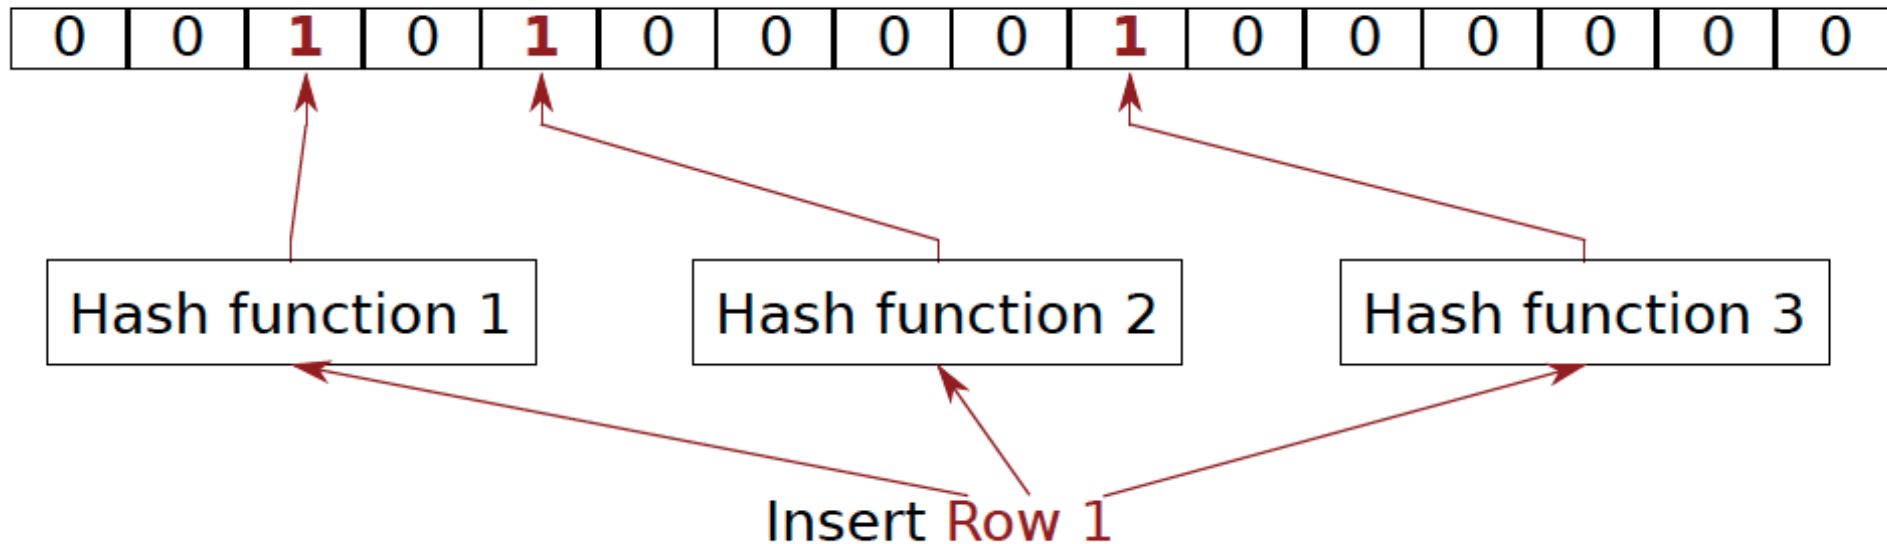

---

- [Bloom, CACM 1970]
- Probabilistic data structure that compactly represents set membership (presence or absence of element in a set)
- Non-approximate set membership: Use 1 bit per element to indicate absence/presence of each element from an element space of  $N$  elements
- Approximate set membership: use a much smaller number of bits and indicate each element's presence/absence with a subset of those bits
  - Some elements map to the bits other elements also map to
- Operations: 1) insert, 2) test, 3) remove all elements

# Bloom Filter Operation Example

---

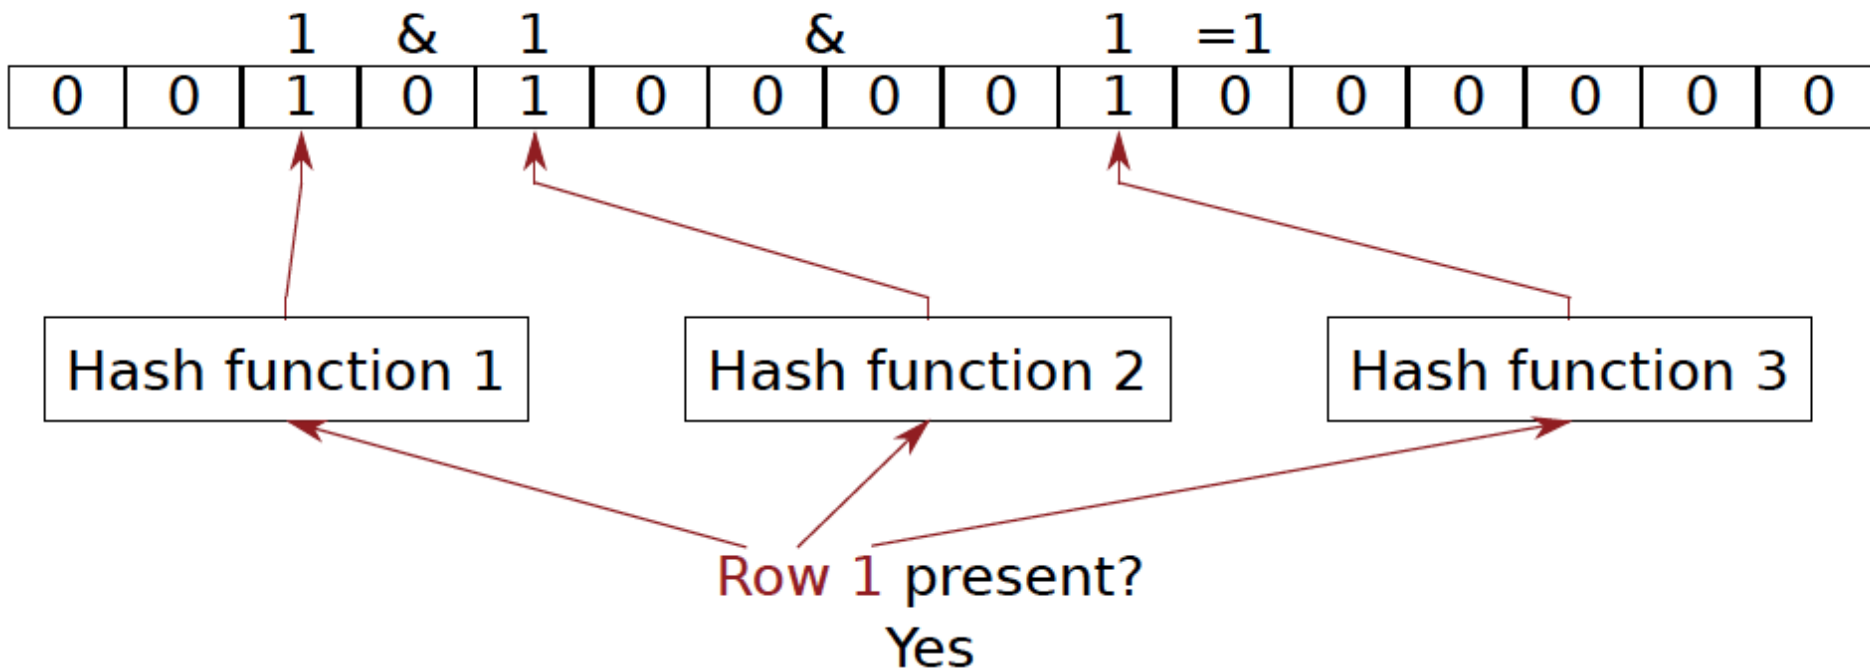

Example with 64-128ms bin:

# Bloom Filter Operation Example

## Space/Time Trade-offs in Hash Coding with Allowable Errors

BURTON H. BLOOM

*Computer Usage Company, Newton Upper Falls, Mass.*

In such applications, it is envisaged that overall performance could be improved by using a smaller core resident hash area in conjunction with the new methods and, when necessary, by using some secondary and perhaps time-consuming test to "catch" the small fraction of errors associated with the new methods. An example is discussed which illustrates possible areas of application for the new methods.

In this paper trade-offs among certain computational factors in hash coding are analyzed. The paradigm problem considered is that of testing a series of messages one-by-one for membership in a given set of messages. Two new hash-coding methods are examined and compared with a particular conventional hash-coding method. The computational factors considered are the size of the hash area (space), the time required to identify a message as a nonmember of the given set (reject time), and an allowable error frequency.

# Bloom Filters: Pros and Cons

---

## ■ Advantages

- + Enables **storage-efficient** representation of set membership
- + Insertion and testing for set membership (presence) are **fast**
- + **No false negatives**: If Bloom Filter says an element is not present in the set, the element must not have been inserted
- + Enables **tradeoffs** between **time** & **storage efficiency** & **false positive rate** (via sizing and hashing)

## ■ Disadvantages

- **False positives**: An element may be deemed to be present in the set by the Bloom Filter but it may never have been inserted

Not the right data structure when you cannot tolerate false positives

# Benefits of Bloom Filters as Refresh Rate Bins

---

- **False positives:** a row may be declared present in the Bloom filter even if it was never inserted
  - **Not a problem:** Refresh some rows more frequently than needed
- **No false negatives:** rows are never refreshed less frequently than needed (no correctness problems)
- **Scalable:** a Bloom filter never overflows (unlike a fixed-size table)
- **Efficient:** No need to store info on a per-row basis; simple hardware → 1.25 KB for 2 filters for 32 GB DRAM system
